Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

The present invention generally relates to a papermaking process in which an aqueous paper pulp containing cellulose pulp and, optionally, also mineral filler, is formed and dried, drainage- and retention-improving chemicals being added to the paper pulp prior to forming.

Papermaking processes of this general type are widely disclosed in the literature.

In the making of different grades of paper using bleached/unbleached mechanical pulps or unbleached chemical pulps, drainage and retention problems are normally encountered. This seems to be because when making special paper grades, high contents of detrimental or trash substances are had in the paper stock. These detrimental and trash substances consist of substances dissolved from the fibre, such as kraft lignin, lignosulphonates, hemicellulose, rosin and salts. In order to counteract the drainage and retention problems, it is possible to use various retention aids available on the market, but the effect of these aids is adversely affected by the detrimental or trash substances present in the stock. This is a well-known problem and has been discussed in the literature, for instance in the Swedish Paper Journal (Svensk Papperstidning) No. 14, 1979, pp. 408-413, and the Swedish Paper Journal No. 12, 1982, pp. 100-106. These basic works have shown that there is a reaction between e.g. anionic lignosulphonate and cationic retention aid, and that a so-called polyelectrolyte complex is formed. Such complexes often have an adverse effect on the drainability of the paper stock.

One object of the present invention therefore is to provide a drainage and retention system which counteracts the drainage and retention problems encountered in papermaking, especially in the making of paper products based on bleached/unbleached mechanical pulps or unbleached chemical pulps. Another object of the invention is to provide a papermaking process providing satisfactory drainage and retention also when using such pulps.

Further objects and advantages of the invention will appear from the following specification and the accompanying drawings. Figs. 1 - 12 are diagrams of the results obtained in the Examples given below.

The invention is based on the surprising discovery that special cationic polymers, in combination with a special inorganic colloid, will give a substantial improvement in respect of drainage and retention on both mechanical and unbleached chemical pulps.

Quite generally, the system according to the invention comprises the step of admixing in the paper stock prior to forming a special combination of chemicals which comprise two components, one anionic and one cationic component. The anionic component is formed of colloidal particles having at least a surface layer of aluminium silicate or aluminium-modified silicic acid. The cationic component is formed of a cationic polyacrylamide. The characterizing features of the invention are stated in the accompanying claims.

It is previously known to use combinations of anionic and cationic components in connection with papermaking. Thus, European Patent EP-B-0 041 056 discloses a binder system where the fibres of the paper are bonded with the aid of a combination of cationic starch and silicic acid sol.

Another known method for improving the properties of a paper product is disclosed in EP-B-0 080 986 in which a binder system is formed of colloidal silicic acid and cationic or amphoteric guar gum.

In a development of the binder systems disclosed in the last-mentioned two patent specifications, use is made of a special inorganic sol which is an aluminium silicate sol or an aluminium-modified silicic acid sol (GE-A-0 185 068, falling within the term. Art. 54 (3) EPC). This special sol has been found to give a particularly notable improvement in the function of the binder. An aluminium oxide-modified silicic acid sol as such has previously been used in connection with papermaking but not in combination with cationic substances. This appears from Swedish patent application 7900587-2.

European patent EP-B-0 020 316 discloses a surface-modified pigment having a surface coating in the form of two layers where one layer consists of an $\text{Al}_2\text{O}_3\text{-SiO}_2$ hydrate gel and the other layer consists of a polymeric binder. As examples of polymeric binders are stated e.g. polyacrylate and cationic polyamides. This patent specification however relates to a pigment and aims at improving the properties of the pigment as an additive in paper or paints. The patent specification is not concerned with modifying the drainage and retention characteristics of a paper pulp.

Finnish Patents FI-C-67 735 and FI-C-67 736 disclose a three-component system for hydrophobic sizing of paper, which comprises a sizing agent, a cationic polymer and an anionic polymer. Examples of sizing agents are rosin acid, activated rosin acid, alkyl ketene dimer, carbamoyl chloride, succinic anhydride, fatty acid anhydride or fatty acid chloride. Examples of cationic polymers are cationic starch, cationic guar gum, polyacrylamide, polyethylene imine, polyamine or polyamide amine. Examples of anionic polymers are colloidal silicic acid, bentonite, carboxymethyl cellulose or carboxylated polyacrylamide. The Examples stated in the patent specifications use bleached sulphate pulp as fibre material in the stock, for which reason the amount of detrimental or trash substances is small. Nothing is mentioned in the patent specifications about the influence of the trash substances on the papermaking process. A preferred pH range of 6 - 8 is stated, which is in contradistinction to the present invention yielding good results within the entire pH range and, thus, also on the acid side, which is of importance when using mechanical stocks and other stocks having a high content of detrimental or trash substances.

The known two-component systems based on one anionic and one cationic component thus mainly serve as binders and have yielded good results on most papermaking stocks, for instance an increased bonding strength of the finished paper. Also, it is possible in some cases on e.g. wood-containing printing papers to

obtain an increase in strength by means of such systems, especially with the system using guar gum and colloidal silicic acid.

It has however been found that these known systems are not fully effective for solving the drainage and retention problems in all types of papermaking stocks. This is particularly notable in stocks containing bleached/unbleached mechanical or unbleached chemical pulps. As mentioned above, this seems to be because cationic starch and cationic or amphoteric guar gum presumably has a tendency to react by preference with the dissolved wood or trash substances, such that the yield of the desired reaction with the inorganic sol is reduced.

If, as in the invention, the cationic starch or the guar gum is replaced by cationic polyacrylamide and the inorganic colloid is a sol the particles of which have at least one surface layer of aluminium silicate or aluminium-modified silicic acid, as indicated above, there is however obtained a considerably higher reaction selectivity to the anionic inorganic colloid, also at high contents of trash substances, especially dissolved wood substances. As will appear from the following Examples, this improvement is extremely manifest.

The greatest improvements obtained with the invention have been observed when the system is used for mechanical pulps or unbleached chemical pulps. However, improvements are also obtained for other types of pulps, such as chemical pulp, e.g. sulphate or sulphite pulp from both hardwood and softwood. The improvements with thermomechanical and mechanical pulps are highly significant. As used herein, the term "cellulosic pulp" and "cellulosic fibres" refer to all types of paper stocks containing chemical pulp, thermomechanical pulp, chemi-thermomechanical pulp, refiner mechanical pulp and groundwood pulp.

The pulp from which the paper is formed may include mineral fillers of conventional types, such as kaolin, bentonite, titanium dioxide, gypsum, chalk, and talc. As used herein, the term "mineral filler" includes, in addition to these fillers, wollastonite and glass fibres and also mineral low-density fillers, such as expanded perlite. The mineral filler is usually added in the form of an aqueous slurry in the conventional concentrations used for such fillers.

As mentioned above, the mineral fillers in the paper may consist of or comprise a low-density or high-bulk filler. The possibility of adding such fillers to conventional paper stocks is limited by factors such as the drainage of the paper stock on the wire and the retentions of the fillers on the wire. It has been discovered that the problems caused by the addition of such fillers can also be counteracted or substantially eliminated by using the system according to the present invention.

In the drainage and retention system according to the invention, the inorganic colloid should consist of colloidal particles having at least a surface layer of aluminium silicate or aluminium-modified silicic acid, such that the surface groups of the particles contain silicon atoms and aluminium atoms in a ratio of from 9.5 : 0.5 to 7.5 : 2.5. The particles of the sol should preferably have a surface area of 50 - 1000 m²/g and more preferably about 200 - 1000 m²/g, the best results having been observed when the surface area has been about 300 - 700 m²/g. The sol has advantageously been stabilized with an alkali. If the sol consists of an aluminium-modified silicic acid, the stabilization with alkali can be performed with an alkali having a molar ratio of SiO₂ : M₂O of from 10 : 1 to 300 : 1, preferably from 15 : 1 to 100 : 1 (M is an ion selected from the group consisting of Na, K, Li and NH₄). It has been established that the colloidal sol particles should have a size of less than 20 nm and preferably an average particle size ranging from about 10 down to 1 nm (a colloidal particle of aluminium-modified silicic acid having a surface area of about 550 m²/g corresponds to an average particle size of about 5.5 nm).

If the colloidal particles consist of a pure aluminium silicate sol, this can be prepared in a known manner by precipitation of water glass with sodium aluminate. Such a sol has homogeneous particles, such that the surfaces of the particles have silicon atoms and aluminium atoms in a ratio of from 9.5 : 0.5 to 7.5 : 2.5. Alternatively, use can be made of an aluminium-modified silicic acid sol, i.e. a sol in which only a surface layer of the surfaces of the sol particles contains both silicon and aluminium atoms. Such an aluminium-modified sol is prepared by modifying the surface of a silicic acid sol with aluminate ions, which is possible presumably because both aluminium and silicon may under suitable conditions assume the coordination number 4 or 6 in relation to oxygen, and because they both have approximately the same atomic diameter. Since the aluminate ion Al(OH)₄⁻¹ is geometrically identical with Si(OH)₄, the ion can be inserted or substituted into the SiO₂ surface, thus generating an aluminium silicate seat having a fixed negative charge. Such an aluminium-modified silicic acid sol is far more stable against gel formation within the pH range 4 - 6 within which unmodified silicic acid sols may gel quickly, and is less sensitive to salt. The production of aluminium-modified silicic acid sols is well known and disclosed in the literature, for example in the book "The Chemistry of Silica" by Ralph K. Iler, John Wiley & Sons, New York, 1979, pp. 407-410.

The modification of the silicic acid sol thus implies that a given amount of sodium aluminate is caused to react at high pH (about 10) with the colloidal silicic acid. This means that the colloidal particles will have surface groups that consist of ≡Al-OH⁻¹. At low pH (4 - 6), these groups are strongly anionic in character. This is in contradistinction to a pure unmodified silicic acid sol where this strong anionic character is not obtained at low pH since silicic acid is a weak acid with pK_a of about 7.

It has been found that the pH of the paper stock in a papermaking process according to the present invention is not particularly critical and may lie in a pH range of 3.5 - 10. Values higher than pH 10 and lower than pH 3.5 are however unsuitable. If, according to known technique, use is made of unmodified silicic acid as inorganic colloid, good results can be obtained only at high pH values within this interval, while in the present invention where use is made of aluminium silicate sol or aluminium-modified silicic acid sol, a satisfactory

result is obtained within the entire pH range. A particular advantage of the present invention thus is that low pH below 7 or 6 can be used.

Other paper chemicals, such as size, alum and the like, can be used, but care must be taken to ensure that the contents of these substances do not become so excessive as to adversely affect the drainage- and retention-improving effects of the system according to the invention.

To achieve the object of the invention, the cationic polyacrylamide is added to the stock in an amount corresponding to 0.005 - 1.5 % by weight, based on the dry substance of the stock. This content range also applies to the inorganic colloid. Lower addition levels do not seem to give any notable improvement, and higher addition levels do not seem to entail such improvement of drainage and retention as would justify the increased costs caused by the raised addition levels.

The invention will be described in more detail hereinbelow in some Examples.

In the Examples described hereinbelow, use was made of the following chemicals:

ORGANOSORB® is a bentonite clay obtained from Allied Chemicals, Great Britain.

ORGANOPOL® is an anionic polyacrylamide obtained from Allied Chemicals, Great Britain.

Different starch products

BMB-190, a cationic starch having an N-content of 0.35 %, obtained from Raisio AB, Sweden.

BMB-165, a cationic starch having an N-content of 0.2 %, obtained from Raisio AB, Sweden.

HKS, a high-cationised starch having an N-content of 1.75 %.

SP-190, an amphoteric starch obtained from Raisio AB, Sweden.

SOLVITOSE® N, a cationic starch having an N-content of 0.2 %, obtained from AB Stadex, Malmö, Sweden.

SOLVITOSE® D9, a cationic starch having an N-content of 0.75 %, obtained from AB Stadex, Malmö, Sweden.

Amylopectin

CATO 210, an amylopectin product having an N-content of 0.23 %, obtained from Lyckeby-National AB, Sweden.

WAXI MAIZE, an amylopectin product having an N-content of 0.31 %, obtained from Laing National, Great Britain.

Polyimine

POLYIMIN SK, obtained from BASF, West Germany.

POLYMIN, SN, obtained from BASF, West Germany.

Guar gum

MEYPROBOND® 120, an amphoteric guar gum, obtained from Meyhall AB, Switzerland.

MEYPROID® 9801, a cationic guar gum product having an N-content of 2 %, obtained from Meyhall AG, Switzerland.

GENDRIV® 158, a cationic guar gum product having an N-content of 1.43 %, obtained from Henkel Corporation, Minneapolis, Minnesota, USA.

GENDRIV® 162, a cationic guar gum product having an N-content of 1.71 %, obtained from Henkel Corporation, Minneapolis, Minnesota, USA.

Polyacrylamide products

PAM I, a polyacrylamide designated XZ 87431 obtained from Dow Chemical Rheinwerk GmbH, Reinmünster, West Germany and having a cationic activity of 0.22 meq/g and an approximate molecular weight of 5 million.

PAM II, a polyacrylamide designated XZ 87409 obtained from Dow Chemical Rheinwerk GmbH, Reinmünster, West Germany and having a cationic activity of 0.50 meq/g and an approximate molecular weight of 5 million.

PAM III, a polyacrylamide designated XZ 87410 obtained from Dow Chemical Rheinwerk GmbH, Reinmünster, West Germany and having a cationic activity of 0.83 meq/g and an approximate molecular weight

of 5 million.

PAM IV, a polyacrylamide designated XZ 87407 obtained from Dow Chemical Rheinwerk GmbH, Reinmünster, West Germany and having a cationic activity of 2.20 meq/g and an approximate molecular weight of 5 million.

5

Polyethylene oxide

- 10 POLYOX COAGULANT, a coagulant obtained from Union Carbide Corporation, USA.
POLYOX WSR 301, a polyethylene oxide product obtained from Union Carbide Corporation, USA.

15 Other products

BUBOND 60, a low-molecular weight product having high cationic activity and obtained from Buckman Laboratories, USA

- 20 BUBOND 65, a high-molecular weight product having high cationic activity and obtained from Buckman Laboratories, USA.

BUFLOCK 171, a low-molecular weight product having high cationic activity and obtained from Buckman Laboratories, USA.

25

EXAMPLE 1

- This Example relates to a drainage test using a Canadian Freeness Tester. The paper grade used was supercalendered magazine paper. The stock comprised 76 % fibre and 24 % filler (C-clay from English China Clay). The fibre fraction of the stock had the following composition:

22 % fully bleached pine sulphate pulp
15 % dithionite-bleached thermomechanical pulp
35 % groundwood pulp
28 % broke.

35

The stock was taken from a commercial magazine papermaking machine and was diluted with white water from the same machine to a stock concentration of 3 g/l. The white water had a specific conductivity of 85 mS/m and a total organic content TOC = 270 mg/l. The pH of the stock was adjusted to 5.5 with diluted sodium hydroxide solution. For different chemical dosages, the drainability of the stock was determined according to SCAN-C 21 : 65 in a Canadian Freeness Tester.

- 40 As inorganic sol, use was made of a 15 % Al-silicic acid sol having a surface area of about 500 m²/g and a ratio of SiO₂ : Na₂O of about 40 and 9 % Al atoms on the sol particle surface which gives 0.46 % on the total solids substance of the sol.

- 45 Tests were carried out with both various polymers alone and various polymers combined with 0.3 % inorganic sol, calculated on dry material. In the tests, 1000 ml of stock suspension was placed in a beaker having an agitator driven at a speed of 800 rpm ("Britt-jar"). In the tests with the various polymers alone, the following sequence of steps was used:

1. Addition of drainage and retention polymer to the stock suspension under agitation.
2. Agitation for 45 sec.
- 50 3. Drainage.

In tests using a combination of polymer and sol, the following sequence of steps was used:

1. Addition of drainage and retention polymer under agitation.
2. Agitation for 30 sec.
- 55 3. Addition of inorganic sol under agitation.
4. Agitation for 15 sec.
5. Drainage.

- 60 Table 1 and Fig. 1 show the results of chemical dosage for obtaining maximum drainability, expressed as millilitre CSF. Fig. 1 shows the considerably improved drainability when using a combination of inorganic sol and polyacrylamide (Tests 5 - 8), and the best prior art systems using cationic starch in combination with inorganic sol (Tests 18, 20, and 22 - 26), and a combination of inorganic sol and guar gum (Tests 15 - 17). The detrimental effect of the trash substances dissolved from the thermomechanical pulp and groundwood pulp is manifest in these known systems as compared with the system according to the invention.

- 65 In another series of tests using the same stock, the concentration of inorganic sol was maintained constant

at 0.3 %, but the added amounts of starch, guar gum or polyacrylamide were varied. The results of these tests are given in Table 2 and illustrated in Figs. 2 and 3. As appears from Table 2 and Figs. 2 and 3, drainage was improved in the two known processes and also in the process according to the invention. Thus, Fig. 2 illustrates the improvements obtained with the known technique as disclosed in European patent specification EP-B-0 041 056 (Tests 28 - 33) and the process as disclosed in European patent specification EP-B-0 080 986 (Tests 34 - 38). However, when using the system according to the invention (Tests 39 - 50), the drainability was substantially improved at lower additions of the polyacrylamide.

10

EXAMPLE 2

This Example relates to a drainage test using mechanical pulps, namely groundwood pulp, chemi-thermomechanical pulp (CTMP), and peroxide-bleached thermomechanical pulp (TMP). The same inorganic sol was used as in Example 1.

Groundwood pulp (spruce) and TMP were taken from two magazine papermaking mills. By centrifugation, the two pulps were concentrated to about 30 % dry solids content. The thermomechanical pulp was dried at room temperature to about 90 % dry solids content. The chemi- thermomechanical pulp (spruce) was taken in the dry state from a pulp-mill and had a dry solids content of about 95 %.

The pulps were placed for a sufficient time in deionized water and thereafter slushed in a wet-slusher (according to SCAN-M2 : 64). After slushing, the pulp suspensions were diluted to 0.3 % (3 g/l) with deionized water. To the resulting stock was added 1.5 g/l $\text{NaSO}_4 \cdot 10\text{H}_2\text{O}$, corresponding to a specific conductivity of about 85 mS/m, such that the specific conductivity was the same as in Example 1, in which white water from a papermaking machine was used.

The pH of the stock suspension was adjusted to 4 or 8 by means of diluted NaOH and H_2SO_4 solutions. Drainage tests according to SCAN-C 21 : 65 were carried out with various PAM products alone and combinations of the various PAM and sol under the same test conditions as in Example 1. The test results are given in Tables 3 - 7 and Figs. 4 - 8.

It clearly appears from these results that a combination of polyacrylamide and inorganic sol gives higher drainage effects than polyacrylamides used alone. The level of the technical effect depends on the pH of the stock, the cationic activity of the polyacrylamide, the chemical character of the pulp, and on the chemical composition of the water phase. In all cases, the improvement obtained by the addition of polyacrylamide is manifest.

The tests accounted for in Table 7 and Fig. 8 were meant to establish the limit values for the addition of the aluminium-modified silicic acid sol. The concentration of the added sol was thus varied from 0.025 % to 1 %. With 0.025 % sol, an improvement in drainability of about 40 - 50 ml CSF was obtained as compared with the use of polyacrylamide alone. Such an effect is likely to occur also at lower values for the addition of the sol, but the improvement will not become as notable. The upper limit has been studied at an addition of up to 1 % (10 kg/ton of paper), but there is nothing to indicate that the effect would be lost at higher addition levels. A practical upper limit therefore is 1.5 % while, for practical reasons, the lower limit is 0.005 % for this chemical. The same values apply to the polyacrylamide chemical.

45 **EXAMPLE 3**

This Example relates to a drainage test using unbleached sulphate pulp with a kappa number of 53, using a Canadian Freeness Tester according to SCAN-C 21 : 65. The sol used was the same as in Example 1.

In this test, 360 g dry pulp was placed in 5 litre deionized water for about 20 h. The pulp was thereafter beaten according to SCAN-C 25 : 76 to a beating degree of about 90 ml CSF. The beating time was about 75 min. The beaten pulp was thereafter diluted with deionized water to a concentration of 3 g/l (0.3 %). 1.5 g/l $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ was thereafter added to the fibre suspension, and the pH of the fibre suspension was adjusted with diluted NaOH or H_2SO_4 to pH 4 or 8.

The other test conditions were the same as in Examples 1 and 2 (order and time for the addition of chemicals, speed and time for agitation).

The results are given in Table 8 and also illustrated in Figs. 9 and 10. The inventive effect clearly appears from these results. The effect is dependent primarily on the pH of the pulp and the chemical composition of the water phase (salt content and presence of dissolved organic substances).

60

EXAMPLE 4

This Example relates to a drainage test for establishing ash retention. The stock used had the same composition as that in Example 1. In this Example, too, use was made of the same inorganic sol as in Example 1.

65

For the retention measurements, use was made of a so-called dynamic dewatering jar ("Britt-jar"), the first 100 ml of the filtrate was collected in a measuring glass. In the measurements, use was made of a wire having a mesh size of 76 μm . The chemical dosage method and the agitation technique were the same as in Examples 1 - 3, and the total time of agitation after chemical dosage was 45 sec. The agitator speed was 800 rpm. The dosage of the colloidal aluminium-modified silicic acid sol was carried out 30 sec. after the dosage of the polyacrylamide.

The retention measurement method is described by K. Britt and J.E. Unbehend in Research Report 75, 1/10, 1981, published by Empire State Paper Research Institute ESPRA, Syracuse, N.Y. 13210, USA.

From the results in Table 9 and Fig. 11 it appears that a higher ash retention is obtained with a combination of polyacrylamide and aluminium-modified silicic acid sol than with polyacrylamide alone.

EXAMPLE 5

This Example relates to a drainage test using groundwood pulp. In the test, use was made of two types of sols, namely the same Al-silicic acid sol as in Example 1 and, as a reference, a pure silicic acid sol in the form of a 15 % sol having a surface area of about 500 m^2/g and a ratio of $\text{SiO}_2 : \text{Na}_2\text{O}$ of about 40.

The groundwood pulp (spruce) was taken from a magazine papermaking mill. By centrifugation, the pulp was concentrated to about 30 % dry solids content. After the pulp had been placed for a sufficient time in deionized water, it was beaten in a wet-slusher (according to SCAN-M2 : 64). After slushing, the pulp suspension was diluted to 0.3 % (3 g/l) with deionized water. To the thus obtained stock was added 1.5 g/l $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$, corresponding to a specific conductivity of about 85 mS/m, such that the specific conductivity was the same as in Example 1, in which white water from a papermaking machine was used.

The pH value of the stock suspension was adjusted to 8 with a diluted NaOH solution. Drainage tests according to SCAN-C21 : 65 were carried out using PAM alone and combinations of PAM and unmodified silicic acid sol or PAM and aluminium-modified silicic acid sol, under the same test conditions as in Example 1. The test results are given in Table 10 and Fig. 12.

It clearly appears from these results that a combination of polyacrylamide and inorganic sol gives improved drainability as compared with polyacrylamide alone and that the aluminium-modified sol gives a markedly improved result as compared with the unmodified pure silicic acid sol.

EXAMPLE 6

In addition to the above-mentioned tests, a comparison was made between drainage tests using extremely high addition levels of polyacrylamide (PAM III) and the same inorganic sol as in Example 1, and at extreme pH values. These drainage tests were conducted in the manner described in Example 1, both on the stock suspension of groundwood pulp described in Example 5 and on a chemical pulp (bleached sulphate). The results are given in Tables 11 and 12.

Claims

1. A papermaking process in which an aqueous paper pulp containing cellulosic pulp and, optionally, also mineral filler, is formed and dried, drainage- and retention-improving chemicals being added to the paper pulp prior to forming, characterized in that the drainage- and retention-improving chemicals added are a cationic polyacrylamide and a sol of colloidal particles having at least a surface layer of aluminium silicate or aluminium-modified silicic acid, such that the surface groups of the particles contain silicon atoms and aluminium atoms in a ratio of from 9.5 : 0.5 to 7.5 : 2.5.
2. Method as claimed in claim 1, characterized in that the cationic polyacrylamide is added in an amount of 0.005 - 1.5 % by weight, calculated on dry paper stock.
3. Process as claimed in claim 1 or 2, characterized in that sol is added in an amount of 0.005-1.5 % by weight, calculated on dry paper stock.
4. Process as claimed in claim 1, 2 or 3, characterized in that the sol has sol particles of a surface area of from about 50 to about 1000 m²/g, preferably from about 300 to about 700 m²/g.
5. Process as claimed in any one of claims 1 - 4, characterized in that the pH of the paper pulp is adjusted to from about 3.5 to about 10.
6. Process as claimed in any one of claims 1 - 5, characterized in that the amount of cellulosic pulp in the paper pulp is adjusted to give a finished paper having at least 50 % by weight of cellulosic fibres.
7. A paper product containing cellulosic fibres, preferably in an amount of at least 50 % by weight, calculated on the paper product, and drainage- and retention-improving chemicals and, optionally, also containing mineral filler, characterized in that the drainage- and retention-improving chemicals comprise a cationic polyacrylamide, colloidal inorganic particles having at least a surface layer of aluminium silicate or aluminium-modified silicic acid, such that the surface groups of the particles contain silicon atoms and aluminium atoms in a ratio of from 9.5 : 0.5 to 7.5 : 2.5.
8. Paper product as claimed in claim 7, characterized in that its content of cationic polyacrylamide and its content of colloidal inorganic particles each is 0.005 - 1.5 % by weight, calculated on the dry solids content of the paper.

Patentansprüche

1. Papierherstellungsverfahren, bei dem eine wäßrige Papiermasse, enthaltend Cellulosezellstoff und gegebenenfalls auch mineralischen Füllstoff, gebildet und getrocknet wird, wobei zu der Papiermasse vor dem Formen Entwässerungs- und Rückhalteverbesserungs-Chemikalien zugesetzt werden, dadurch gekennzeichnet, daß die zugesetzten Entwässerungs- und Rückhalteverbesserungs-Chemikalien ein kationisches Polyacrylamid und ein Sol von Kolloidteilchen mit mindestens einer Oberflächenschicht von Aluminiumsilikat oder Aluminiummodifizierter Kieselsäure, so daß die Oberflächengruppen der Teilchen Siliciumatome und Aluminiumatome in einem Verhältnis von 9,5 : 0,5 bis 7,5 : 2,5 enthalten, umfassen.
2. Verfahren gemäß Anspruch 1, dadurch gekennzeichnet, daß das kationische Polyacrylamid in einer Menge von 0,005 bis 1,5 Gew.-%, berechnet auf den trockenen Papierstoff, zugesetzt wird.
3. Verfahren gemäß Anspruch 1 oder 2, dadurch gekennzeichnet, daß das Sol in einer Menge von 0,005 bis 1,5 Gew.-%, berechnet auf den trockenen Papierstoff, zugesetzt wird.
4. Verfahren gemäß Anspruch 1, 2 oder 3, dadurch gekennzeichnet, daß das Sol Solteilchen mit einer Oberfläche von etwa 50 bis etwa 1000 m²/g, vorzugsweise von etwa 300 bis etwa 700 m²/g, hat.
5. Verfahren gemäß einem der Ansprüche 1 bis 4, dadurch gekennzeichnet, daß das pH des Papierbreis von etwa 3,5 bis etwa 10 eingestellt wird.
6. Verfahren gemäß einem der Ansprüche 1 bis 5, dadurch gekennzeichnet, daß die Menge an Cellulosezellstoff in der Papiermasse eingestellt wird, um ein fertiges Papier mit wenigstens 50 Gew.-% Cellulosefasern zu ergeben.
7. Papierprodukt, enthaltend Cellulosefasern, vorzugsweise in einer Menge von wenigstens 50 Gew.-%, berechnet auf das Papierprodukt, und Entwässerungs- und Rückhalteverbesserungs-Chemikalien und gegebenenfalls auch einen mineralischen Füllstoff enthaltend, dadurch gekennzeichnet, daß die Entwässerungs- und Rückhalte-Verbesserungs-Chemikalien ein kationisches Polyacrylamid, kolloidale, anorganische Teilchen mit wenigstens einer Oberflächenschicht von Aluminiumsilikat oder Aluminiummodifizierter Kieselsäure umfassen, so daß die Oberflächengruppen der Teilchen Siliciumatome und Aluminiumatome in einem Verhältnis von 9,5 : 0,5 bis 7,5 : 2,5 enthalten.
8. Papierprodukt gemäß Anspruch 7, dadurch gekennzeichnet, daß sein Gehalt an kationischem Polyacrylamid und sein Gehalt an kolloidalen, anorganischen Teilchen jeweils 0,005 bis 1,5 Gew.-%, berechnet auf den Trockenfeststoffgehalt des Papiers, ist.

Revendications

1. Procédé de fabrication de papier dans lequel une pâte à papier aqueuse contenant une pâte cellulosique et, éventuellement, également une charge minérale est formée et séchée, des produits chimiques améliorant l'égouttage et la rétention étant ajoutés à la pâte à papier avant le formage, caractérisé en ce que les produits chimiques ajoutés, améliorant l'égouttage et la rétention, sont un polyacrylamide cationique et un sol de particules colloïdales ayant au moins une couche de surface de silicate d'aluminium ou d'acide silicique modifié à l'aluminium, tel que les groupes de surface des particules contiennent des atomes de silicium et des atomes d'aluminium dans un rapport de 9,5 : 0,5 à 7,5 : 2,5.
2. Procédé selon la revendication 1, caractérisé en ce que le polyacrylamide cationique est ajouté dans une proportion de 0,005 à 1,5 % en poids, calculé par rapport à la pâte à papier sèche.
3. Procédé selon la revendication 1 ou 2, caractérisé en ce que le sol est ajouté dans une proportion de 0,005 à 1,5 % en poids, calculé par rapport à la pâte à papier sèche.
4. Procédé selon les revendications 1, 2 ou 3, caractérisé en ce que le sol comprend des particules de sol ayant une surface spécifique d'environ 50 à environ 1.000 m²/g, de préférence d'environ 300 à environ 700 m²/g.
5. Procédé selon l'une quelconque des revendications 1 à 4, caractérisé en ce que le pH de la pâte à papier est ajusté d'environ 3,5 à environ 10.
6. Procédé selon l'une quelconque des revendications 1 à 5, caractérisé en ce que la proportion de pâte cellulosique dans la pâte à papier est ajustée de façon à produire un papier fini ayant au moins 50 % en poids de fibres cellulosiques.
7. Papier contenant des fibres cellulosiques, de préférence dans une proportion d'au moins 50 % en poids, calculé par rapport au papier, et des produits chimiques améliorant l'égouttage et la rétention et, éventuellement, contenant également une charge minérale, caractérisé en ce que les produits chimiques améliorant l'égouttage et la rétention comprennent un polyacrylamide cationique, des particules minérales colloïdales ayant au moins une couche de surface de silicate d'aluminium ou d'acide silicique modifié à l'aluminium, tels que les groupes de surface des particules contiennent des atomes de silicium et des atomes d'aluminium dans un rapport de 9,5 : 0,5 à 7,5 : 2,5.
8. Papier selon la revendication 7, caractérisé en ce que sa teneur en polyacrylamide cationique et sa teneur en particules minérales colloïdales sont chacune de 0,005 à 1,5 % en poids, calculé par rapport à la teneur en matières solides sèches du papier.
